

## Example 5

# De la Vallée Poussin means and nested spaces

For a set of dilation matrices this demo illustrates nested spaces build by scaling functions of de la Vallée Poussin type.

## Loading the Library

The MPAWL is located in the parent directory (see MPAWL.m) in order to load the library, we add its path to **\$Path**.

```
In[1]:= $Path = Join[$Path, {ParentDirectory[NotebookDirectory[]]}];  
SetDirectory[NotebookDirectory[]]; (*Set to actual directory*)  
Needs["MPAWL`"];
```

Both constructions, the generalized de la Vallée Poussin means and their subspaces are investigated in Chapter 4 in [1] (in german) or [2], up to their ability to form an MRA.

## De la Vallée Poussin mean

The de la Vallée Poussin means from the one-dimensional case are given in their Fourier coefficients as samplings of a linear function, more precisely a pyramid function, for example using

```
In[4]:= ? pyramidFunction
```

```
"pyramidFunction[α,x]\n\nThe d-dimensional analog of the pyramid function, the de la Vallée\nPoussin mean are build on. These are here shrunk for generality\nonto the symmetric unit cube, i.e.  
having a support from  $-\frac{1}{2}-\alpha$  to  $1/2+\alpha$  in each dimension.\n\nα may be a nonnegative number  
less than  $\frac{1}{2}$  or an array of nd elements containing such numbers, where d is the length of x."
```

```
In[5]:= Plot[pyramidFunction[1 / 8, x], {x, -1, 1}]
```

and similar for higher dimensions, where they may have different decays, e.g.

```
In[6]:= Plot3D[pyramidFunction[{1 / 8, 1 / 4}, {x, y}], {x, -1, 1}, {y, -1, 1}]
```

These are then sampled at the points `Transpose[Inverse[mM]].k`, where  $k$  is an integer vector. In general, the de la Vallée Poussin means can be obtained by any function  $g$ , as can be seen in the `::usage`. Though for the pyramidal cases, there is a shorthand: When  $g$  is a value or a vector representing  $\alpha$ , where even more for the higher dimensions  $\alpha$  may be a value indicating, that each dimension has the same decay. For these, the support is known and we don't have to specify that option.

Furthermore the function can also directly compute the corresponding Bracket sums:

In[7]:= **? delaValleePoussinMean**

delaValleePoussinMean[g,mM]

Generate the de la Vallée Poussin Kernel  $\varphi_M^0$  in Fourier coefficients based on the function g and the matrix mM. While mM is an integer regular matrix of dimension d\*d, the function g has to fulfill the three properties:

- 1) non-negativity
- 2) strictly positive on the shifted (symmetric) unit cube
- 3) For every x the sum over all integer shifts g(x+z) equals 1.

For simplicity g might be given as a nonnegative number  $t \leq \frac{1}{2}$  which corresponds to the pyramidal (tensor product of 1D de la Vallée Poussin means) function, where the support is  $-\frac{1}{2}t$  to  $\frac{1}{2}t$  in each dimension.

Or an array of such numbers, performing the same idea with different width in each direction, hence the array must be the same dimension as each dimension of mM.

### Options

BracketSums  $\rightarrow$  *False* | *True*

Compute the Bracket sums and return an array {ckV, BSV} consisting of the Fourier coefficients ckV and the Bracket Sums BSV of the kernel.

Orthonormalize  $\rightarrow$  *True* | *False*

Perform an orthonormalization of the translates of the kernel with respect to mM.

validateMatrix  $\rightarrow$  *True* | *False*

whether to perform a check (via **isMatrixValid**) on the matrix mM.

File  $\rightarrow$  *None* | String | {String,String}

save the Fourier coefficients of the kernel to a file. If the Bracket sums are computed too, there have to be two string, the first representing the kernel, the second the Bracket sums to be saved.

Support  $\rightarrow$   $\frac{1}{2}$  | p

specifies the support of g, if it is given as a function, to extend the shifted unit cube by p in each dimension. This can also be given as a d-dimensional vector, where each entry is nonnegative and smaller than  $\frac{1}{2}$ .

Debug  $\rightarrow$  "None" | "Text" | "Time"

or any combination of these Words in one String (i.e. concatenated via "&") to produce intermediate results, indicate progress and display computation times.

For simplicity lets first look at a diagonal matrix. The coefficients are computed and the array does at least cover the complete support. Let's look at the image of the Fourier coefficients. As in the previous example, the origin is in the middle of the array

In[8]:= **mM = 32 IdentityMatrix[2];**

In[9]:= **ckφM = delaValleePoussinMean[  
  pyramidFunction[{1/14, 1/14}, #] &, mM, Support  $\rightarrow$  {1/14, 1/14}];  
  max = (Dimensions[ckφM] - 1) / 2; origin = max + 1;**

Where we specify the datarange

```
In[11]:= ListPointPlot3D[ckφM, DataRange → Transpose[{-max, max}]]
```

This is the same as using

```
In[12]:= ListPointPlot3D[deLaValleePoussinMean[{1 / 14, 1 / 14}, mM],  
DataRange → Transpose[{-max, max}]]
```

Or even shorter for this case due to the same decay in both dimensions

```
In[13]:= ListPointPlot3D[delaValleePoussinMean[1 / 14, mM],
  DataRange → Transpose[{-max, max}]]
```

The same works for arbitrary matrices, where we omit the axis

```
In[14]:= M2 = {{16, 12}, {0, 16}};
ckφM2 = delaValleePoussinMean[1 / 14, M2];
max2 = (Dimensions[ckφM2] - 1) / 2; origin2 = max2 + 1;

In[17]:= ListPointPlot3D[ckφM2, DataRange → Transpose[{-max2, max2}]]
```

```
In[18]:= φ2[x_] := Sum[ckφM2[[Sequence@@({k1, k2} + origin2)]] Exp[I {k1, k2}.x],
  {k1, -max2[[1]], max2[[1]]}, {k2, -max2[[2]], max2[[2]]}];
```

```
In[19]:= φ2Term = Simplify[φ2[{x, y}]];
```

```
In[20]:= Plot3D[Chop[ $\phi$ 2Term], {x, - $\pi$ ,  $\pi$ }, {y, - $\pi$ ,  $\pi$ }, PlotRange → All, MaxRecursion → 6]
```

Where the corresponding Dirichlet Kernel looks like the following (and is the limit case for  $\alpha \rightarrow 0$ )

```
In[21]:= ckDM2 = DirichletKernel[M2];
maxD = (Dimensions[ckDM2] - 1) / 2; originD = maxD + 1;

In[23]:= d[x_] := Sum[ ckDM2[[Sequence@@({k1, k2} + originD)]] Exp[I {k1, k2}.x] ,
  {k1, -maxD[[1]], maxD[[1]]}, {k2, -maxD[[2]], maxD[[2]]}];

In[24]:= dTerm = Simplify[d[{x, y}]];

In[25]:= Plot3D[Chop[dTerm], {x, - $\pi$ ,  $\pi$ }, {y, - $\pi$ ,  $\pi$ }, PlotRange → All]
```

## Subspaces

For any function  $\phi_M$  and a factorization of the regular matrix  $M = JN$  into integer matrices  $J$  and  $N$ , we would like to obtain a function  $\phi_N$  which is in the space of translates, i.e.  $\text{span}\{\phi_M(\cdot - 2\pi y), y \in \mathcal{P}(M)\}$ . These are characterized by either a set of coefficients with respect to these shifts and hence a value for each point of the **pattern[M]** or similarly (in their discrete Fourier transform) on the generating set. First, the main matrices for factorization are in the dyadic case given by

In[26]:= ? dilationMatrix2D

dilationMatrix2D[letter]

represents the 2-dimensional dilation matrices available in the de la Vallée Poussin case. These are named by letters and an additional sign for some matrices, in total these are: "X", "Y", "D", "Y+", "Y-", "X+" and "X-"

In[27]:= **Table[MatrixForm[dilationMatrix2D[L]],**  
**{L, {"X", "Y", "D", "Y+", "Y-", "X+", "X-"}},]**

Out[27]=  $\left\{ \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix}, \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 1 \\ 0 & 2 \end{pmatrix}, \begin{pmatrix} 1 & -1 \\ 0 & 2 \end{pmatrix}, \begin{pmatrix} 2 & 0 \\ 1 & 1 \end{pmatrix}, \begin{pmatrix} 2 & 0 \\ -1 & 1 \end{pmatrix} \right\}$

We use

In[28]:= **mN = Inverse[dilationMatrix2D["X"]].M2**

Out[28]=  $\{\{8, 6\}, \{0, 16\}\}$

and define the smaller de la Vallée Poussin mean by its (discrete Fourier transform of the) space coefficients. again a function g models the decay of the coefficients of  $\varphi_N$ . Furthermore, in this dyadic case, we obtain one wavelet, whose translates (with respect to **pattern[mN]**) form the orthogonal complement of the translates of  $\varphi_N$  in the bigger space  $\varphi_M$ .

In[29]:= **? delaValleePoussinSubspaces**

delaValleePoussinSubspaces[g,mM,mJ]

For any dyadic dilation matrix mJ and a function g fulfilling the properties:

- 1) non-negativity
- 2) strictly positive on the shifted (symmetric) unit cube
- 3) For every x the sum over all integer shifts g(x+z) equals 1.

this method divides the mM-invariant space V (having dimension  $m=|\text{Det}[mM]|$ ) into two orthogonal subspaces by returning two coefficient arrays, whose Fourier transforms are weights to the sum of translates of any function, that spans V with its translates. Both functions provide linear independence with respect to  $mN = \text{Inverse}[mJ].mM$

For simplicity g might be given as a nonnegative number  $t \leq \frac{1}{2}$  which corresponds to the pyramidal (tensor product of 1D de la Vallée Poussin means) function, where the support is  $-\frac{1}{2}-t$  to  $\frac{1}{2}+t$  in each dimension.

#### Options

Orthonormalize  $\rightarrow$  True | False

Perform an orthonormalization of the translates of both functions with respect to mN.

Validate  $\rightarrow$  True | False

whether to perform a check (via **isMatrixValid**) on the matrix mM, mJ and mN.

File  $\rightarrow$  None | {String,String}

save the coefficients of both functions to a file each.

Debug  $\rightarrow$  "None" | "Text" | "Time"

or any combination of these Words in one String (i.e. concatenated via "&") to produce intermediate results, indicate progress and display computation times.

Again these coefficients characterizing  $\varphi_N$  in  $\varphi_M$  are given in the frequency domain.

In[30]:= **{coeffS, coeffW} = delaValleePoussinSubspaces[1 / 14, M2, dilationMatrix2D["X"]];**

we can reconstruct the Fourier coefficients using the function from the translation invariant spaces

Example 4

In[31]:= **? getFourierFromSpace**

getFourierFromSpace[coefficients, ckSpace, originIndex, mM]

The coefficients represent the Fourier transform of the weights which applied to the translates --- with respect to mM -- of a function  $\varphi$  result in a function  $f$  and  $\varphi$  with its Fourier coefficients ckSpace (where originIndex is the index representing the origin), this function reconstructs the Fourier coefficients of  $f$ .

#### Options

Validate  $\rightarrow$  True | False

whether to perform a check (via **isMatrixValid**) on the matrix mM and the check, whether the Origin is in Range of the Fourier coefficients.

In[32]:= **ck $\varphi$ N = getFourierFromSpace[coeffS, ck $\varphi$ M2, origin2, M2];**

In[33]:=  **$\varphi$ N[x\_] := Sum[ ck $\varphi$ N[[Sequence@@({k<sub>1</sub>, k<sub>2</sub>} + origin2)]] Exp[I {k<sub>1</sub>, k<sub>2</sub>}.x] ,  
{k<sub>1</sub>, -max2[[1]], max2[[1]]}, {k<sub>2</sub>, -max2[[2]], max2[[2]]}];**

In[34]:=  **$\varphi$ NTerm = Simplify[ $\varphi$ N[{x, y}]];**

In[35]:= **Plot3D[Chop[ $\varphi$ NTerm], {x, - $\pi$ ,  $\pi$ }, {y, - $\pi$ ,  $\pi$ }, PlotRange  $\rightarrow$  All, MaxRecursion  $\rightarrow$  6]**

And the same for the corresponding wavelet

In[36]:= **ck $\psi$ N = getFourierFromSpace[coeffW, ck $\varphi$ M2, origin2, M2];**

In[37]:=  **$\psi$ N[x\_] := Sum[ ck $\psi$ N[[Sequence@@({k<sub>1</sub>, k<sub>2</sub>} + origin2)]] Exp[I {k<sub>1</sub>, k<sub>2</sub>}.x] ,  
{k<sub>1</sub>, -max2[[1]], max2[[1]]}, {k<sub>2</sub>, -max2[[2]], max2[[2]]}];**

In[38]:=  **$\psi$ NTerm = Simplify[ $\psi$ N[{x, y}]];**

```
In[39]:= Plot3D[Chop[ $\psi$ NTerm], {x, - $\pi$ ,  $\pi$ }, {y, - $\pi$ ,  $\pi$ }, PlotRange -> All, MaxRecursion -> 6]
```
